Individual Preparation (The Interactive Space)	This aspect assesses your individual technical mastery of Unity development skills. The goal is to demonstrate that you can independently translate a physical space into an interactive 'Digital Twin' in VR. We look strictly at the Technical Execution as described in the Individual Assignment briefing.	No Unity project, video demo, or reference photos submitted.	The submission does not meet the core requirements. The application does not start. A build is absent (the application does not start on a headset). The script for the interaction (the 'Event') is missing or does not work.	You have delivered a working VR environment that meets all basic requirements, the build runs on a headset. The space has been recognizably recreated based on your own photos. The player can walk around via Teleportation and pick up objects via the XR Grab Interactable. There is a World Space UI that triggers a visible change in the world via a custom script, and the code works with acceptable errors.	The execution shows neatness and attention to detail. You used Baked lighting to enhance the visuals. Your scripts are readable and follow conventions such as clear variable names. Your video displays a neatly organized project folder. The interactions are complex, and logically embedded in the context of the space.	You meet all criteria for 'Good' (8). A convincing 'Digital Twin'. The VR experience is optimized without performance issues. Your code is modular and commented. You went beyond the basic requirements by building multiple complex interactions (e.g. Hand-tracking, and poke interactions) that together form a complete and logical narrative within the space.	2
Research (Literature, Context Analysis, User Research)	For this aspect, we expect you not to build on assumptions, but to base your design on thorough research. This includes both desk research and user research according to the Human-Centred Design (HCD) cycle. The literature study informs on the theoretical background of your application, and the benefits of learning in XR. This leads to logical research questions, and hypotheses. Your user research informs the design choices.	No research has been conducted or documented, or the quality of the research is poor.	**Active participation during the Kick-off with product owners is missing presentation.** The research questions are vague, not based on desk and user research. The literature review is superficial or irrelevant to the topic. No proper sources have been used. There is no clear application of the User-Centred Design process. The quality of the research is poor, which makes translation of the data to design choices difficult.	There are clear research questions, and the literature research is revelant to the topic. Proper sources have been used to answer the research questions. The user research has been conducted following human centered design methods, and includes proof including but not limited to a persona and a user journey map. Both the literature study and user study inform design decisions, and documented.	Your analysis is systematic, data-driven, shows a link to relevant literature and properly documented. You apply all HDCI and Design of Interactive Systems analysis methodologies to arrive at deeper insights, and provide proof. Your literature research links didactics to specific XR properties.	You meet all criteria for 'Good' (8). You show professional insight by combining different methodologies (triangulation), and apply research methods that go beyond the learning activities in year 1. The research forms the integral basis of your design choices. The literature study is concise and covers (at least) learning in XR, and learning content relevant to the project topic. Your research is in a pre-publication ready state of applied research.	3
Concept & Design Rationale	Here we assess the quality of your design and its substantiation. We expect you to explicitly apply HCI principles and Data Visualization principles. You show the evolution of your design via iterative methodologies such as Storyboarding. The design takes into account how users process information (Mental Models). We look at how you guide the user in a 3D world without them getting lost or overstimulated.	Missing: No design documentation, script, or storyboard present.	The ideation phase that lead to your final design has not been conducted using relevant methods, and proof of ideation is missing. The narrative description or design is vague or illogical. The storyboard is unclear. The simulation design choices are unsubstantiated by theory and research.	**Providing only the baseline track-specific principles limits you to this assessment level; you must define 2-3 additional, research-based requirements to score higher.** The ideation phase has been completed using relevant methodologies and has been properly documented. There is a complete narrative for the training, and basic storyboards are present. You explain what you have made, but the design choices have not been linked to theory or user research.	The ideation phase is easy to follow, and several relevant methods have been applied, properly documented and justified. The narrative is clear and logical, and represents what happens in the entire simulation. The storyboard shows a clear use case scenario. Design choices and properly applied design principles are explicitly justified from theory. This is demonstrated using visuals of your design, linking them to theoretical concepts.	You meet all criteria for 'Good' (8). The integration of theory and design is seamless, making it a blueprint for an investment ready simulation.	3
Realization, Immersive Quality & Evaluation (Prototyping to Product)	This aspect assesses the quality of the translation from abstract idea to a tangible, educational XR experience and its validation. We expect you to have used Prototyping techniques as an iterative design tool. You demonstrate that you master the specific components of XR: Spatial Audio and Lighting direct attention, and interactions contribute to Embodied Cognition. The technical realization must be comfortable (Latency and frame rate in order). It is important that you do not base the quality of your product on assumptions but validate it through Usability Testing. You use the results of these tests to demonstrate that your design goals (e.g. Usability or Presence) have been achieved.	Missing: No working prototype and build, no video submitted, and/or no evaluation carried out.	There is a large gap between concept and execution. The realization shows no traces of prototyping. The application performs poorly technically: there is noticeable Latency. Interactions lack Feedback (visual/auditory/haptic). No form of user testing has been done.	The concept has been translated into a working product: a build which functions on an XR device. And iterative design processes have been applied. Proof of different prototypes and evaluations are provided. The basic functionality is there including navigation and interactions, and the Input Devices are used correctly. A Formative Usability Evaluation has been carried out.	Craftsmanship is visible. The environment actively guides the user and interactions have the right Interaction Fidelity. You have gone through an Iterative Design process where results from previous tests are visibly processed and properly reflected on. The simulation contains a logical learning experience, with specific learning tasks that can be completed from start to finish. The 'Cycle of Interaction' proceeds smoothly for the user.	You meet all criteria for 'Good' (8). High-Fidelity Realization & Validation. You have scientifically substantiated the quality of your application by using validated measuring instruments, including relevant questionnaires and qualitative methods, analyzed this data. The results are used to improve the quality of your simulation or provide recommendations for future iterations. The technical realization seamlessly supports the didactic goals. The build can run on an XR device, stand-alone.	2
Reporting & Presentation	This aspect assesses your level of dissemination. You are required to complete two benchmark moments: the interim presentation (week 6) and the final live demo (week 10). Important: Active participation from every group member is required for both presentations. Additionally, we assess the Research Report (portfolio). The report must contain the mandatory parts as described in the project description.	Missing: No portfolio submitted and/or absence at the pitch and/or absence at the final demo.	**The interim presentation OR final demo did not take place.** The report is messy and does not follow the provided structure. No clear distinction is made between assumptions and facts. References to sources are missing or done poorly.	Both the interim presentation and the demo are performed. The report follows the provided structure. Citing sources is correct.	The interim presentation and final demo are complete and well structured. They are performed in a professional way. The report is written with high quality, and easy to follow.	You meet all criteria for 'Good' (8). The report is of publishable quality. You show ownership of the data. You reflect critically on the limitations of your research and make recommendations for follow-up steps.	1
